

Angiotensin-neprilysin inhibition in heart failure across the spectrum of ejection fraction

A prespecified pooled analysis of the PARADIGM-HF and
PARAGON-HF trials

Scott D. Solomon, MD; Lars Lund, MD; Milton Packer, MD; Jean Rouleau, MD;
Michael Zile, MD; Karl Swedberg, MD; Nancy Sweitzer, MD; Akshay Desai, MD;
Lars Kober, MD; Gerard Linssen, MD; Inder Anand, MD; Martin Lefkowitz, MD;
Victor Shi, MD; Adel Rizkala, PharmD; John J. V. McMurray, MD
for the PARADIGM-HF and PARAGON-HF Investigators

Disclosures

- Dr. Solomon has received research grants from Alnylam, Amgen, AstraZeneca, Bellerophon, Bayer, BMS, Celladon, Cytokinetics, Eidos, Gilead, GSK, Ionis, Lone Star Heart, Mesoblast, MyoKardia, NIH/NHLBI, Novartis, Sanofi Pasteur, Theracos, and has consulted for Akros, Alnylam, Amgen, Arena, AstraZeneca, Bayer, BMS, Cardior, Corvia, Cytokinetics, Daiichi-Sankyo, Gilead, GSK, Ironwood, Merck, Myokardia, Novartis, Roche, Takeda, Theracos, Quantum Genetics, Cardurion, AoBiome, Janssen, Cardiac Dimensions, Tenaya
- PARADIGM-HF and PARAGON-HF were funded by Novartis

Background and Rationale

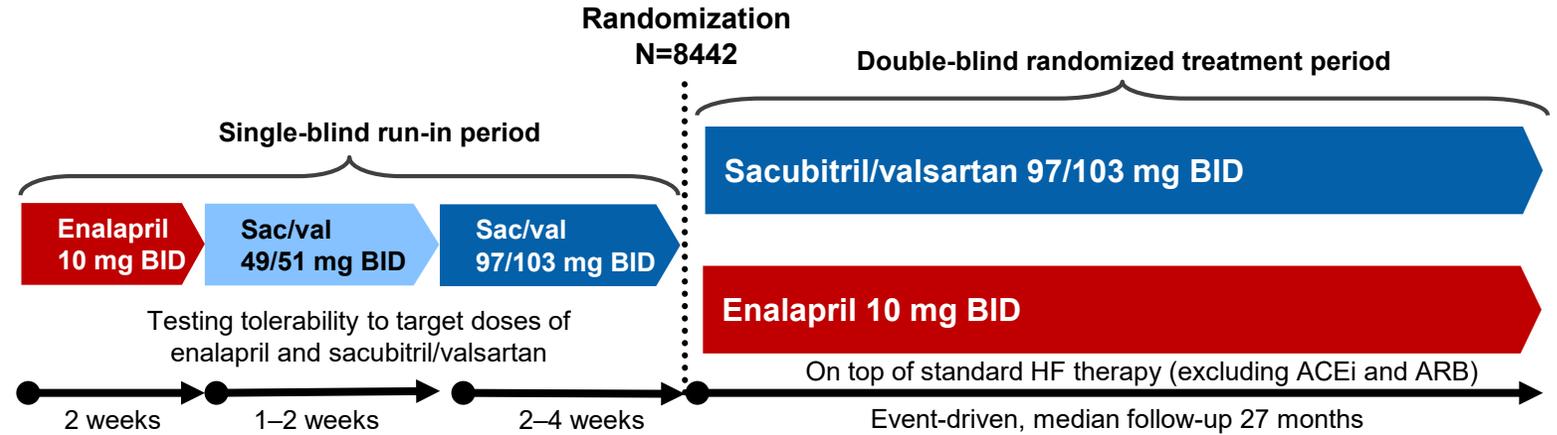

- Although heart failure with reduced ejection fraction (HFrEF) has multiple etiologies, virtually all patients with this disorder respond to several classes of pharmacologic therapies that have, in clinical trials, been shown to contribute to step-wise reductions in morbidity and mortality.
- Nevertheless, few options have been available for patients with ejection fraction above the “reduced” range, generally considered 40% or less.
- Sacubitril/valsartan has now been compared with a renin-angiotensin-system (RAS) inhibitor alone in two similarly designed large outcomes trials of patients with reduced and preserved LVEF, permitting examination of its effects across the full spectrum of LVEF.

Entry criteria

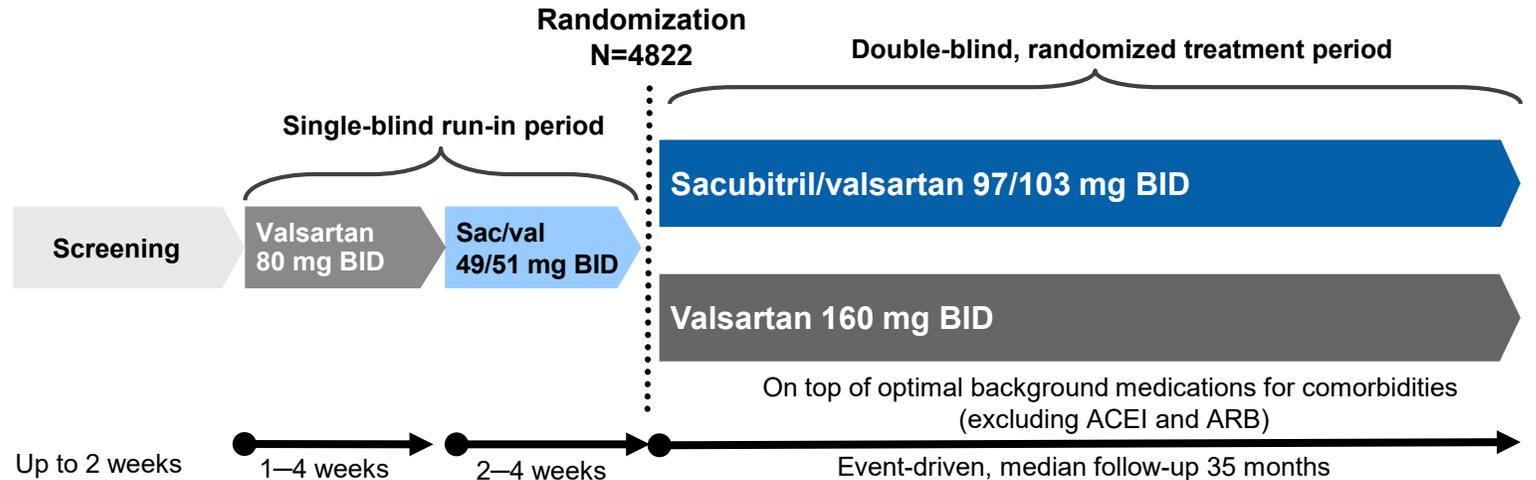

PARADIGM-HF

- Age ≥ 18 years
- Signs/symptoms of heart failure (NYHA II-IV)
- LVEF $\leq 40\%$
- Elevation in NT-proBNP (400/600 or BNP 100/150 depending on prior HF hospitalization)

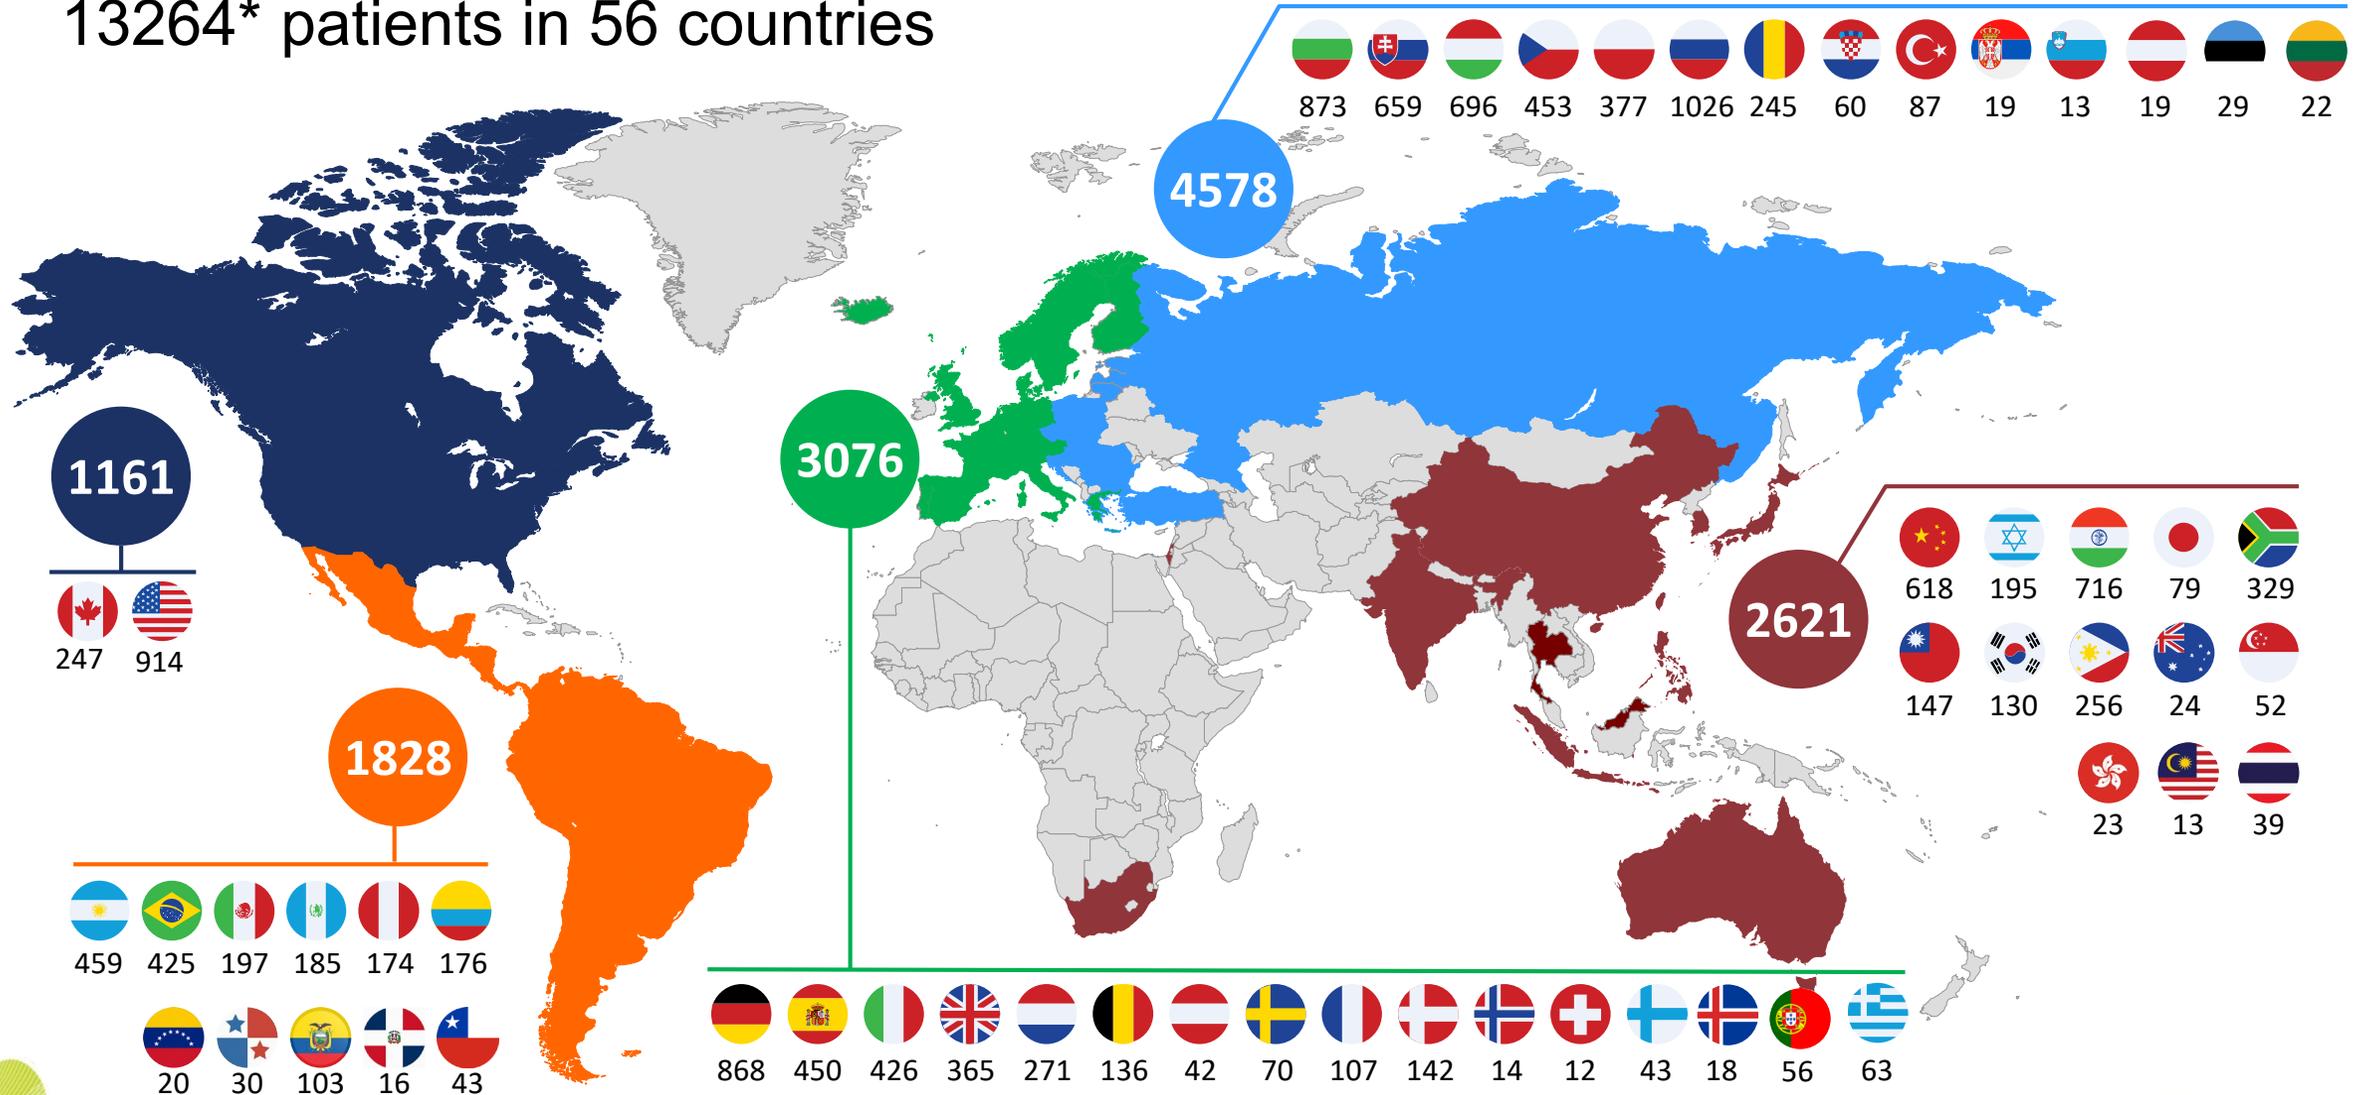

PARAGON-HF

- Age ≥ 50 years
- Signs/symptoms of heart failure (NYHA II-IV)
- LVEF $\geq 45\%$
- Elevation in NT-proBNP (200/600 or 300/900 depending on prior HF hospitalization and AF)
- Structural heart disease (LVH or LAE)
- No prior LVEF $< 40\%$

PARAGON-HF and PARADIGM-HF combined

13264* patients in 56 countries

*46 patients from PARADIGM-HF and 26 from PARAGON-HF excluded from final analysis

Methodologic Considerations

- 13,195 patients from two trials
- Ejection fractions measured at sites (exact numbers required)
- Pooling results from PARADIGM-HF and PARAGON-HF was prespecified prior to unblinding
- We divided patients into 10 point EF groups ($\leq 22.5\%$, >22.5 to 32.5% , $>32.5\%$ to 42.5% , $>42.5\%$ to 52.5% , $>52.5\%$ to 62.5% , >62.5) avoiding cut-offs on multiples of 5 because of substantial digit preference
- We compared treatment effects for those randomized to sacubitril/valsartan compared with RAS inhibitor (enalapril or valsartan) overall (stratifying by study) and within each EF group, and using continuous analyses
- We assessed both time to first composite of CV death or heart failure hospitalization (PARADIGM primary endpoint) and the composite of total heart failure hospitalizations and cardiovascular death (PARAGON primary endpoint) across the spectrum of LVEF

Conclusions

- In this large, patient-level analysis of two pivotal trials we observed overall benefit comparing sacubitril/valsartan to RAS inhibition alone.
- These findings were driven by an observed benefit in patients with chronic HF and LVEF below the “normal” range, with women deriving benefit to a higher LVEF than men.
- These data suggest that the therapeutic response to sacubitril/valsartan may be heterogeneous with respect to ejection fraction, and that the benefits of sacubitril/valsartan, compared with a RAS inhibitor alone, appear to extend to patients with heart failure and mildly reduced ejection fraction, with women perhaps benefiting to higher ejection fractions than men.
